

◀ **TEMPIETTO OF SAN PIETRO**

Designed by Donato Bramante, the Tempietto of San Pietro in Montorio in Rome is a defining work of the Renaissance. Comprising a circular colonnade supporting a cylindrical drum and hemispherical dome, it embodies the Classical idea of harmony.

△ **DOMED CEILING**

The underside of a dome was typically articulated, or segmented, in one of two ways: architecturally with sunken panels of diminishing size called coffers, or, as seen in the Tempietto, figuratively via mural painting in fresco (painting on wet plaster).

▷ **PILASTERS**

Taking the form of a column flattened against a wall, the pilaster is a key element in Renaissance architecture. Without any structural purpose, it is used as a decorative element in articulating the extent of a wall.

RENAISSANCE DOMES

While Gothic architecture made use of the spire to top a cathedral or church, Renaissance architects favored the dome for its symmetry, geometrical purity, and structural stability.
