

STING IN THE TAIL

The tail club was made of huge osteoderms—bones that grew within the skin. To support its weight, the rear of the tail was strengthened by a framework of tough tendons and connective tissues, which helped keep the tail end rigid and clear of the ground.

STATS AND FACTS

Large ankylosaurs such as *Euoplocephalus* were at risk of overheating. To prevent this, *Euoplocephalus* had a complex nasal passage that it used to cool or warm the air it breathed, which helped keep its body temperature constant.

CLUB IMPACT

Generating up to 1.6 tons (1.5 tonnes) of force on impact, larger tail clubs could have shattered bone.

WEIGHT

An adult *Euoplocephalus* could weigh 2.2 tons (2 tonnes).

Spikes on *Euoplocephalus*'s back provided extra defense.
