

ARGENTINOSAURUS

SAUROPODOMORPHS

With small heads perched upon long necks, these herbivores were the largest dinosaurs to walk the planet. Some that evolved later, such as *Argentinosaurus*, grew to record-breaking sizes—nearly seven times as large as an African elephant.

CERATOPSIANS

The plant-eating ceratopsians are instantly recognizable by their parrotlike beaks. In the Cretaceous, some forms evolved elaborate crests and horns, which were probably used to attract mates.

TRICERATOPS

TYRANNOSAURUS

THEROPODS

The most diverse of the dinosaur groups, theropods gave rise to modern birds. Most theropods were carnivores, but some may have had a plant-based diet.

PACHYCEPHALOSAURS

These two-legged dinosaurs are easily identifiable by the extremely thick skulls that protected their brain from violent clashes when competing for mates or defending against predators.

PACHYCEPHALOSAURUS

STEGOSAURS

These generally mid-sized herbivores had rows of plates and spikes running along their backs. Only a few kinds of stegosaurs were left by the Early Cretaceous Period.

STEGOSAURUS

ANKYLOSAURS

These stocky dinosaurs had wide bodies protected by extensive armor and bony scales called osteoderms. Some later forms, such as *Euoplocephalus*, evolved large, bone-crushing tail clubs.

EUOPOLOCEPHALUS

OURANOSAURUS

ORNITHOPODS

A large body and big nostrils were features of this group of plant-eating dinosaurs. Most experts think that they were social animals, and some even evolved flashy crests for display.
