

RHAMPHORHYNCHUS

Toothy beak

A small fish was found in *Rhamphorhynchus*'s throat, which it may have swallowed just before it was caught itself.

Rhamphorhynchus had a bellyful of fish remains.

Long wing bones

Tailbone

ASPIDORHYNCHUS

Accidental entanglement

Rhamphorhynchus probably caught fish when swimming or by swooping close to the surface of the water, grabbing small prey with its curved beak. On one such hunting expedition, this pterosaur's movements may have disturbed the surface of the water, catching the attention of *Aspidorhynchus*. As the fish raised its head to catch this potential prey, its long snout got stuck in the pterosaur's wing, leading to the fatal accident.

UV FINDINGS

Scientists have been able to study this fossil in greater detail by shining ultraviolet (UV) light on it. This revealed *Rhamphorhynchus*'s stomach contents and showed exactly how *Aspidorhynchus* was stuck in the pterosaur's wing membrane.
