

FOSSIL NEST

This fossilized nest was discovered in a Mongolian desert in the 1920s. Containing long, narrow eggs, this nest was initially believed to belong to *Protoceratops*. A fossilized theropod discovered near the nest was assumed to have died while trying to raid it and was named *Oviraptor*—meaning “egg thief.” However, further research revealed that the nest, in fact, belonged to the theropod, which probably died while tending to its eggs.
