

Gentle feeder

Despite its size, *Leedsichthys* mostly ate tiny marine organisms, such as microscopic zooplankton. Projections called gill rakers in its gills helped this creature feed in a manner similar to modern-day filter feeders, such as some sharks and whales. As *Leedsichthys* swam through the oceans, the gill rakers combed miniscule creatures out of the water, ready to be swallowed whole.

Fossils indicate that *Leedsichthys* had a large skull.

Large pectoral fins allowed *Leedsichthys* to swim efficiently and keep itself afloat.
