

BEAK OF BRISTLES

As this fossil cast shows, the pterosaur *Pterodaustro* had long, thin, bristly teeth in its beak. Unlike modern birds, many prehistoric flying reptiles had teeth, but *Pterodaustro*'s were uniquely adapted for filter feeding. *Pterodaustro* probably fed on the tiny shrimp and algae that lived in its lakeside habitat, using its sievelike beak to filter them out of the water. Like modern flamingos, *Pterodaustro* nested along the edges of the lake.
