

Dangerous teeth

The serrations on the sides of *Tyrannosaurus*'s teeth helped spread the force of its bite, giving it the power to shatter bone. However, not all attacks were successful, and the fossils of several herbivores show healed *Tyrannosaurus* bite marks on their bones. These fleeing *Edmontosaurus* still have a chance of survival.

BONE CRUSHER

TYRANNOSAURUS

With its huge jaws and gigantic teeth, *Tyrannosaurus* had the strongest bite of any land creature that has ever lived. To deal with the pressure of such a powerful bite, its skull was bigger and stronger than any other meat-eating theropod. The back of the skull was wide, which gave the jaw-closing muscles space to contract with as much force as possible. The power this generated enabled *Tyrannosaurus* to sink its deadly teeth deep into the flesh of its prey.
