Phototransistor optocouplers

Vishay Intertechnology has introduced the VOx619A series phototransistor optocouplers designed for low-power operation and stable signal isolation in high-

temperature environments. The devices operate with a forward current of just 0.5mA, about 50% lower than previous generations, while maintaining a stable current transfer ratio for accurate signal transmission. The optocouplers target industrial controls, energy meters, telecom equipment, micro-mobility systems, and consumer electronics requiring efficient galvanic isolation.

Battery-free in-tire sensing system

BANF and Silicon Labs have developed a battery-free in-tire sensing system that turns vehicle tyres into real-time data platforms for autonomous and

connected vehicles. The solution combines an ultra-low-power Bluetooth Low Energy SoC with an in-tire sensor module capable of sampling tire data at up to 4kHz and performing edge processing inside the tire. It

monitors parameters such as acceleration, pressure, temperature, and tread depth while transmitting only processed alerts to the vehicle. Developed through collaboration between BANF and Silicon Labs, the platform uses magnetic-resonance wireless power transfer, eliminating batteries and enabling continuous operation in harsh tire environments.

EMBEDDED

Embedded 3D camera

e-con Systems has launched the DepthVista Helix, a 1.2MP 3D continuous-wave indirect time-of-flight (iToF) camera featuring on-device

depth processing for robotics and industrial automation. Engineered by e-con Systems,

with development spanning teams in Chennai and California, the camera performs on-chip depth computation, achieving depth accuracy of less than 1% across short- and mid-range distances. Designed for AMRs, bin-picking robots, palletisation, and industrial safety, the platform integrates with Nvidia Jetson systems and includes a software SDK to accelerate deployment in machine-vision applications.

System-on-module

MYIR has launched the MYC-YM62LX system-on-module along with the MYD-YM62LX development board, a compact platform designed to accelerate prototyping for industrial

and embedded systems. The solution, engineered by MYIR, enables developers to rapidly build and test devices such as HMI panels, PLC controllers, IoT gateways, and medical equipment, thereby shortening development cycles and accelerating industrial product deployment.

DC-DC converters

The RMOD4000 series of DC-DC converters, designed for electric machines, aims to improve power control and efficiency in motor-driven systems. The converter regulates DC

voltage supplied to electric machines, enabling precise speed and torque control while reducing energy losses. Such converters convert one DC voltage level to another using switching power electronics, enabling efficient

power delivery under varying operating conditions.

Developed

for modern electric drive systems, the design helps integrate batteries, renewable sources, and power electronics with motors used in electric vehicles and industrial equipment. By using high-efficiency switching techniques and advanced semiconductor devices, the converter improves performance, reduces heat generation, and supports compact, high-power motor drive architectures.

Development board

Arduino's VENTUNO Q is a development board for running AI on edge devices with real-time control. It combines a Qualcomm Dragonwing IQ8

series AI processor with a neural processing unit delivering up to 40 TOPS for AI workloads, including generative models, and an

STM32H5 microcontroller for motor control and actuation. Running AI locally instead of in the cloud supports voice assistants with local language models, gesture-based mirrors, speech kiosks, robotics tasks such as pick-and-place arms and user-following machines, and monitoring systems for security video analysis, traffic processing, or defect detection using vision-language models.
