At the same time, vision-based applications across sectors such as smart surveillance, automated manufacturing, precision agriculture, and intelligent mobility remain largely untapped. If Indian businesses do not transition towards integrated hardware solutions, there is a risk of missing a substantial market opportunity to leverage AI-enabled edge applications across sectors that have traditionally relied on generic hardware platforms.

Vision Computing SoCs focus on market-ready solutions

For India, the real opportunity with Vision Computing SoCs is not merely about catching up with global trends. It lies in redefining how embedded intelligence can power growth within India's diverse and rapidly expanding economy.

Unlike traditional systems that add AI capabilities onto hardware as an afterthought, Vision Computing SoCs embed intelligence directly at the core of devices. This integration

addresses multiple industry bottlenecks in ways that are particularly relevant to India's scale, diversity, and cost dynamics.

The cost equation also tilts favourably. By investing in the localised manufacturing of Vision Computing SoCs, India can reduce its dependency on high-cost imports, thereby easing supply chain risks while moving closer to achieving its \$300 billion electronics output target by 2026. At the same time, the growth of this sector could accelerate the development of a new generation of engineers trained in advanced hardware innovation.

Another promising outcome is the potential for local innovation. With the right ecosystem, Vision Computing SoCs could unlock a wave of "vision-first" startups developing products for smart farming, portable healthcare diagnostics, industrial automation, and autonomous mobility. These are not futuristic concepts; they are market-ready solutions awaiting the right technology push.

The future India is prepared to lead

India's journey in electronics and embedded systems is not merely about replicating global trends. The focus is on building strategic capability and strengthening technological self-reliance.

With domestic chipmaking gaining momentum and collaborative initiatives such as the US-India Bharat Semi Fab laying critical infrastructure foundations, the possibility of homegrown vision-centric chips is now within tangible reach.

Vision Computing SoCs, combined with India's growing design talent, supportive policy framework, and entrepreneurial energy, could place the country at the forefront of the embedded intelligence revolution. The question before India's electronics sector is no longer whether it can catch up with the world, but whether it can move ahead of it. **EFY**
