3 ARVO: The Answer To Product Authenticity Challenges

1 THIS AI WEARABLE STARTUP IS BUILDING YOUR SECOND BRAIN

In a world overflowing with information, NeoSapien presents an AI wearable designed to transform memory into a dynamic, evolving intelligence.

NeoSapien Private Limited is a Bengaluru-based startup founded in 2024 by Dhananjay Yadav and Aryan Yadav.

The company has developed an AI-powered wearable that acts as a user's second brain, capturing everyday conversations, transcribing them, and building an intelligent relationship graph that connects people, facts, priorities, and commitments over time.

Dhananjay notes that, unlike traditional meeting note-taking apps limited to scheduled virtual calls, NeoSapien's device functions as an always-on ambient conversational intelligence system that captures both offline interactions, including informal conversations, and online discussions.

It recognises different speakers through advanced speaker diarisation, transcribes conversations with high accuracy, and continues to learn from each interaction. Over time, it maps relationships between users and their contacts, organising contextual information that can be accessed and retrieved as needed.

The startup states that the device functions without internet connectivity,

capturing offline conversations and meetings and transferring data to the user's phone via Bluetooth.

However, advanced processing—such as transcript generation, speaker identification, and the extraction of tasks, priorities, and calendar invites—occurs in the

cloud and requires internet access. If connectivity is unavailable, the mobile application securely stores the data and processes it once the connection is restored. This ensures that conversations and associated data are retained.

The startup reports a speaker accuracy rate of 98.26 per cent across Indic languages such as Hindi, Kannada, and Gujarati, along with a numerical accuracy of 91.59 per cent.

Audio is processed in encrypted memory and not persistently stored. Raw audio is discarded after transcription, reducing storage requirements. According to Dhananjay, even years' worth of transcribed data occupies significantly less digital space than recorded files.

The intelligence layer is built on a proprietary knowledge graph algorithm that connects conversations over time. If a user meets someone multiple times, the system tracks prior discussions, identifies pending tasks, and generates contextual outputs such as pre-read documents, draft emails, or calendar blocks.

The system is described as encrypted, with data
