NDEF support and declares approximately 8kB user memory. Alternatively, open the CC file editor from the More menu and configure the CC file as shown in Fig. 7 or refer to Table 2. If the energy-harvesting feature is used to power an LED or another external circuit, the energy-harvesting resistor settings can also be configured from the same menu.

Writing the vCard data

The vCard data must now be written to the NFC chip so that, whenever the business card is tapped on an NFC-enabled smartphone or tablet, the stored contact information is shared automatically. Although the

ST25 NFC tap app can be used to write NDEF records, the NFC tools app provides a simpler interface.

Open the NFC tools app and select Write→Add a Record→Contact (vCard). Enter the required name, company, designation, phone number, email address, website, and other contact details. Additional NDEF records, such as a website URL, email address, phone call, SMS message, or text message, can also be added.

In this system, the primary record is the vCard, while

the secondary record is a website URL. When the card is tapped, the smartphone first imports the contact details and then opens the specified website in the web browser. Fig. 8 shows the process of writing the vCard data to the NFC IC of the business card.

Testing

The NFC business card is now ready for use. Whenever the card is brought near an NFC-enabled smartphone or tablet, it automatically transfers the stored vCard contact information. Since a website URL has also been programmed as a secondary NDEF record, the smartphone opens the specified website in the web browser immediately after importing the contact details.

Fig. 9 shows the NFC business card being scanned with a smartphone and the contact information successfully getting transferred from the card. **EFY**
