

World's smallest AI-powered bone conduction microphones

The UPM01 and UPM02 are vibration-processing units (VPUs), also known as bone conduction microphones (BCMs). They are MEMS vibration

sensor platforms. When paired with the UP201 dual-core RISC-V AI MCU, they form Upbeat Technology's 'Tiny AI Engine,' enabling on-device AI processing in space-constrained designs. The platform combines vibration sensing and bone-conduction voice capture in one system, supporting audio capture and machine monitoring applications. It uses a dual-microphone architecture that integrates a bone-conduction microphone with a conventional air microphone to improve voice pickup in noisy environments.

Real-time fault detector for EMI/EMC, soft errors, and digital faults

GreenIPCore has introduced a fault detector that identifies EMI/EMC issues, soft errors, and digital faults in real time. It is designed for reliability

problems in electronic systems where electrical noise, interference, and radiation can

cause failures, unstable operation, and data corruption. The device monitors system behaviour during operation and detects abnormal conditions caused by external or internal electrical disturbances. It tracks EMI/EMC events as they occur and flags performance changes associated with noise or signal disruption. It correlates environmental noise with system output to help

engineers understand how interference affects circuit behaviour in real conditions. A key feature is fault retention, in which fault signals are preserved after system recovery, allowing engineers to analyse failure patterns over time rather than losing data after stabilisation.

Design tool to help refine power stage design early

onsemi announced Elite Pairing Studio, a design tool that helps engineers identify combinations of silicon carbide (SiC) MOSFETs and gate drivers based on application needs. It helps engi-

neers compare pairing behaviour and trade-offs and supports development of power electronics designs. Elite Pairing Studio compares multiple pairings to reduce iteration count and help refine power stage design earlier in development, reducing design risk and development time. The tool runs on onsemi.com. It evaluates gate driver and SiC MOSFET combinations using equations and performance models. The evaluation method can be inspected by users. The tool provides outputs for each pairing, including switching timing, gate-voltage and current waveforms, voltage overshoot relative to device limits, and switching energy loss, such as turn-on and turn-off energy. These outputs help engineers compare switching behaviour, EMI risk, and reliability margin.

Surface-mount fuse with 14,000A interrupting rating

Littelfuse has introduced the NANO2 surface-mount 708 series fuse. It is the first Littelfuse surface-mount fuse

with a 14,000A interrupting rating at 80V DC. The fuse is designed for 48V DC power systems used in AI servers,

hyperscale data centres, and high-density power distribution setups. As power levels increase and PCB space decreases, designers use larger through-hole or bolt-down fuses. It is used to protect circuits exposed to high fault currents while

supporting denser board layouts and automated manufacturing processes. The 708 series is intended for overcurrent protection in power distribution units, power shelves, battery backup units, and power supply units. It is used in AI server systems, networking equipment, and data centre infrastructure. It also applies to renewable energy systems and battery management systems where high-power protection is needed.

3D scanner that works with a smartphone

Creality launched Pika, a 3D scanner developed with Orbbec. Powered by Orbbec's technologies, Pika combines 3D scanning, AI computing, and a portable design into a single device. Pika is

designed for mobility and workflow use. It can work with a smartphone

without a PC, enabling scanning. It includes a display for scan preview and a battery for use. It is designed for operation for users across design, engineering, and content creation. The device uses a global shutter 3D camera system to reduce motion blur during handheld scanning. It supports up to 40FPS line-laser scanning and up to 20FPS infrared scanning in smartphone mode. Pika integrates 7-line blue laser scanning and infrared structured-light scanning into a single system.
