

they do, the implications of their actions, and how they can change if they choose to. In my work on understanding human behaviour, I treat the human mind not as a finished product but as a dynamic system that requires constant ‘debugging.’ Just as a computer cannot boot without its Basic Input/Output System (BIOS), a human being cannot function without a core set of values. In my effort to understand values, the definition that emerged is: “*Values are the beliefs that one holds within oneself*

which govern one’s behaviour in any given context. Some of these beliefs are known, while others are not yet.” This ‘human BIOS’ forms the invisible logic layer behind every decision, every line of code, and every strategic pivot within a technology company.

The audit of intent. In the high-stakes environment of 2026, where the race for AI supremacy is often measured in weeks, we rarely stop to audit the intent behind our innovation. We need an assessment process that peels back the layers of ‘what’ we are building to reveal the ‘why.’

- *The question.* Is this project an act of contribution to mankind, or an act of conquest for the ego?

- *The consequence.* If the intent is rooted in a desire for dominance or short-term greed, that ‘signal’ will be amplified by the AI.

The diagnostic process. The LOI Framework provides a structured way to probe these internal behaviour systems. It shifts the technologist’s focus from the data sheet to the internal reality.

- *Reflection as a probe.* Just as an engineer uses an oscilloscope to find noise in a circuit, we use reflection to identify noise in our values.

- *Identifying value-deficient.* Over time, corporate pressure can cause a drift in our original purpose. LOI helps individuals and teams recalibrate to their internal reference point: the non-negotiable principles that define their integrity.

When we ignore this internal compass, we create a directional crisis. We assume that we can fix the moral consequences of our technology later. But with AI, later may be too late. The success of the machine is tethered to the clarity of the human who initiates the first spark.

The cost of value-deficient

In the rapid race towards 2026’s milestones in machine intelligence, many tech companies are

accumulating what I call an ethical debt. Similar to technical debt, this is the practice of ignoring moral warnings and long-term social consequences in favour of immediate scaling and market dominance.

The greed trap. When greed directs AI, the technology is inevitably used to exclude rather than include. We see this when life-extension research is gated by wealth or when resource-management systems are optimised for the few at the expense of the many. Greed acts as a filter that narrows the vast potential of AI, transforming an invention built upon thousands of years of human work into a tool for a single generation’s profit.

The ego bottleneck. The ‘ego’ is perhaps the most dangerous bottleneck in the high-tech sector. When a leader’s ego is the primary driver, AI becomes a tool for surveillance and control rather than empowerment. The desire for ‘global first’ status can lead to cutting corners on safety protocols. In this state, the human component is no longer guiding the machine; it is using the machine to validate its own sense of importance.

The recipe for disaster. Pure technological progress combined with a ‘value-deficient’ heart is a catastrophic recipe. We are effectively building a high-speed train with no brakes, driven by someone looking only into the rear-view mirror of their own self-interest.

- *The conflict.* Innovation requires risk, but wisdom requires restraint.

- *The consequence.* If we do not address these primitive human drivers, we risk a ‘systemic crash’ that doesn’t just affect a company’s stock price but the very longevity of the human species itself.

Policy-makers and leadership must recognise that the consequences of machine intelligence are too vast to be left to uncorrected human impulses. The ‘human component’ is not a soft variable; it
