

United States and Taiwan.

Garima explains that the company generates revenue from one-time hardware sales, implementation charges, and annual subscription fees for its intelligence platform. For existing and older buildings, Enlite also offers Automation as a Service under multi-year contracts.

The startup has sold nearly 10,000 hardware units to date and expects cumulative revenue of about ₹450 million by the end of the current financial year. They currently employ around 120 people.

The company plans to expand further into infrastructure automation, data centres, pharmaceutical

Garima Bharadwaj, Co-Founder & CTO, Enlite Research Private Limited

facilities, public infrastructure, and industrial projects. Parallel

investments in wireless technology, analytics, and intelligent control systems will continue to strengthen its platform.

While explaining the meaning of Enlite, Garima shares that it originated from the combination of energy and light, reflecting the company's early focus on intelligent lighting and efficiency. As the company's scope expanded well beyond lighting into deep, full-stack building technology, the name evolved to represent clarity, intelligence, and forward looking innovation across complex physical systems.

2 FOUR-LEGGED ROBOTS THAT CAN MOVE ACROSS ANY TERRAIN

India's first commercial four-legged robot is redefining industrial operations, executing hazardous tasks and powering advanced research with robots purpose-built for real-world environments.

In 2019, Aditya Pratap Singh Rajawat began exploring legged robots at IIT Kanpur, working alongside Prof. Shakti S. Gupta under the guidance of Prof. Mangal Kothari and collaborating with defence research labs. The initial work focused on creating lab prototypes. After graduating, he joined Jaguar Land Rover but remained closely connected with the IIT Kanpur team at the Mobile Robotics Lab. Together, they identified a gap in India: almost no deployable robots and only a few groups exploring advanced robotics. Seeing the opportunity, they decided to transform their lab prototypes into commercial products. In March 2023, xTerra Robotics was established in Kanpur. 'x' stands for any variable, while 'Terra' represents terrain, together symbolising robots designed to navigate any environment.

One of their key products is the Svan M2, a four-legged robot dog. This is being developed as India's

SVAN M2 with the Cobot C1 mounted on it

first commercial quadruped robot. Quadruped means four-legged, and it has been used across various research organisations in India for conducting research in human-machine collaboration, advanced control design, and adding autonomous applications for industries. This product is essential for replacing humans or supporting humans in dull, dirty, and dangerous tasks. With various sensors mounted on the robot head, it can detect gas leaks, identify anomalies on

industrial factory floors, and support defence applications by enabling defence security and surveillance at borders.

Building hardware comes with its own challenges. "We initially designed parts based on theoretical understanding or optimised approaches. When we took these designs to manufacturers, we realised that the required precision and accuracy were difficult to achieve. We then

partnered with an aerospace-grade manufacturer who could deliver higher quality. Even then, the first iterations were not perfect. This created a feedback loop between us. Through multiple iterations, we were able to build something repeatable and consistent for production," says Aditya.

Software development for these robots presents its own set of challenges. We have written everything from the first line of code to the complete system that runs on the
