1 MCS CARGAR MAKING FAST CHARGING SIMPLER AND PORTABLE

The startup has developed portable, flexible EV fast-charging technology, removing dependence on fixed stations.

The climate technology startup, MCS Cargar Private Limited, was founded in 2019 by Raj Anupam and Kayavan Shah to address the challenge of electric vehicle charging infrastructure in India.

The startup has developed portable, flexible EV fast-charging technology, removing dependence on fixed stations. Its solution enables the deployment of charging infrastructure wherever required, rather than requiring users to visit dedicated locations.

The company builds portable fast-charging machines with power capacities ranging from 30kW to 180kW. These chargers can operate in multiple configurations, including on-grid, off-grid, solar-powered, and hybrid systems.

Raj explains that the company manufactures portable chargers designed for easy relocation. For instance, a charger used in a residential area during night-time can be moved to commercial or corporate locations during the day, if required.

These chargers require three-phase electrical supply, which is readily available in almost all residential and commercial buildings. In most

cases, installation involves connecting a submeter to the existing electrical panel. This eliminates the need for heavy civil work or major infrastructure upgrades, making deployment simpler and cost-effective.

The startup operates primarily as an original equipment manufacturer (OEM), designing and producing

portable charging machines. Its customers include charge point operators, electric vehicle fleet operators, commercial real estate owners, corporate parking facilities, and public charging location operators.

The company has developed its own technology platform and communication system for the chargers. "Our system enables direct

payment through the Unified Payments Interface (UPI). Drivers can scan and pay via UPI without downloading an app or maintaining a digital wallet. The charger communicates locally and continues operating even during temporary internet outages. Charging stops automatically once the prepaid amount is exhausted. Operators can also use the software platform to receive payments directly into their accounts," Raj explains.

From a technology standpoint, the company holds several intellectual property assets, including a utility patent related to its charging platform and multiple design patents. The technology emphasises modularity and scalability, enabling the system to efficiently support a range of electric applications.

The startup claims its
