

chargers are largely manufactured in India, with the platform positioned as a 100 per cent 'Made in India' technology solution. Approximately 70 per cent of the components are produced in-house, including control systems, software, and system integration. Some specialised components, such as charging guns and certain electronic chips, are sourced from Germany to ensure reliability. Research and development, testing, and algorithm development are conducted internally by the company's engineering team.

The startup is headquartered in Ahmedabad and operates with a team of around 12-13 members. While some fabrication work is outsourced, the core technological development remains in-house.

Cargar began commercial sales of its chargers in August 2025, following several pilot deployments across the country. Since then, the company has sold around 30-40 units. Its chargers are currently deployed in regions such as Maharashtra, Delhi NCR, Bengaluru, and Gujarat. The starting price of the chargers is approximately ₹400,000, depending on configuration and capacity.

Like many technology startups, the company faced challenges, including product development hurdles, market readiness, and the need to align innovation with real-world demand. Persistence, strong belief in the technology, and continuous customer feedback helped refine the product and bring

it to market.

Raj explains that the company name 'Cargar' is derived from the Spanish word that means 'to charge' and carries a Hindi connotation of efficiency and impact. The company's long-term vision is to make charging accessible everywhere, enabling faster adoption of electric vehicles across India.

Looking ahead, Cargar plans to continue investing in technology development. The company is working on innovations like hybrid systems combining grid and alternative power sources, solar-integrated fast chargers to reduce emissions, and intelligent systems that analyse driving and charging patterns to optimise charger deployment.

2 INNO 91 GREEN TECHNOLOGIES ELIMINATES ENERGY LOSSES, ONE DEVICE AT A TIME

From chargers to heavy industrial machinery, this Indian deep-tech startup is tackling one of the most overlooked sources of power wastage.

Inno 91 Green Technologies has developed a hardware-based intelligent power control solution that can function as an embedded module inside devices, a retrofit switch for existing infrastructure, or a plug-in adaptor for consumer use. The solution automatically cuts off power when devices are idle and restores it instantly when activity resumes, eliminating unnecessary electricity consumption at the source.

Across homes, offices, and industrial facilities, countless plugged-in devices continue to draw power even when idle. This silent consumption increases electricity bills, reduces equipment lifespan, and contributes to avoidable energy loss. According to the company, its solution acts as an intelligent energy gatekeeper that continuously monitors device behaviour and

The power-saving adaptor

disconnects power when no active load is detected, intervening only when energy is being wasted.

At the core of the innovation

is a feedback-based power control architecture that uses real-time load sensing and adaptive switching logic to determine whether a device is actively consuming power or operating in an idle state. Once an idle condition is detected, power is disconnected and restored instantly when usage resumes. The key challenge was ensuring reliable performance across applications, from low-voltage consumer electronics such as mobile chargers to high-load industrial systems, including cranes weighing up to 25 tons—without compromising safety or performance.

Co-founded by Saurabh Tiwari, CEO, and Prateek Warjurkar, CTO, the company was established in 2016 after identifying a significant gap in energy efficiency solutions in India. Early funding from the founders' families supported the
