

An aerial photograph showing a vast expanse of melting sea ice in the Arctic. The ice is fragmented into large, irregular floes of varying sizes, separated by dark, open water. The ice floes have a textured, crystalline appearance with some areas showing a light blue tint. The overall scene conveys a sense of rapid environmental change and the loss of the ice habitat.

Melting ice

Climate change is heating up the Arctic quicker than anywhere else in the world. As sea ice melts, polar bears move onto land with limited access to seals, their primary food source. Without seals, polar bears are at real risk of starvation. If nothing is done, the global population of polar bears could halve to 10,000 by 2050.
