

Primates

Most primates have grasping hands and feet and forward-facing eyes. The group includes monkeys, apes, lemurs, bushbabies, and tarsiers.

Bushbabies, also known as galagos, have excellent night vision and hearing. They can also jump up to 6½ ft (2 m) vertically.

Living in forest treetops, marmosets use their long teeth to chew holes in tree trunks and branches to feed on the gum inside.

Chimpanzees belong to a family of primates called the great apes, which also includes gorillas, orangutans, and humans. They are intelligent, highly social apes that feed on the ground and in trees.

Rodents and rabbits

Rodents make up more than two-fifths of the world's mammal species. Like rabbits and hares, they gnaw their food with their large incisor teeth, which grow nonstop.

Squirrels use their keen sense of smell to locate nuts they buried previously. Many have bushy tails that they use for balance.

Hares and rabbits are related to rodents. To get more nutrients from their food, they digest it twice—by eating their own dung.

Many mice and rats breed at a rapid rate, producing up to 12 young every six weeks or so.

The capybara is the world's largest rodent, weighing up to 145 lb (65 kg). It escapes predators by swimming.

Pangolins

A pangolin is covered with protective, overlapping scales. Pangolins feed on ants and termites and do not have teeth.

A tree pangolin's grasping tail anchors the animal when climbing and feeding in trees.
