

Horses and relatives

Tapirs, horses, and rhinos are hoofed mammals, or ungulates, with an uneven number of toes. Tapirs and rhinos are usually solitary, but horses and their relatives live mainly in herds, relying on speed and endurance to escape danger.

Tapirs use their prehensile trunks to pluck fruit from branches.

Zebras belong to the horse family. Their stripes may encourage them to form social bonds and groom one another.

Rhino horns can grow up to 5 ft (1.5 m) long. Females use theirs to protect their young, while males use them to battle attackers.

Antelopes, deer, and relatives

Most hoofed mammals, or ungulates, belong to this group, which includes many types of wild sheep, goats, and cattle. These mammals have an even number of toes and many have long, slender legs. The majority live entirely on plant food.

The giraffe is the world's tallest animal and can reach leaves up to 16 ft (5 m) above the ground.

Male deer use their bony antlers when fighting over females. They grow new ones every year.

Gerenuks, a type of antelope, often stand up on their hind legs to reach leaves on tall bushes that other species cannot reach.

A camel can travel up to 100 miles (160 km) across the desert using the water it produces from the fat in its hump.

Whales

Ranging in size from porpoises to blue whales—Earth's largest animals—whales breathe through blowholes and swim with flippers and tail flukes.

Baleen whales have mouths that are full of fibrous baleen plates, which work like sieves to filter their food from the water.

Toothed whales include dolphins, porpoises, and sperm whales. Many use echolocation to find their prey.
