

Jumping spider

**Jumping spiders** have eight simple eyes: four on the front of their faces and four on top of their heads. Their many eyes help them accurately judge distances, so they can leap right on top of their prey.

Blue-bottle fly

Have you ever tried to swat a fly? **Flies** can see movements up to five times faster than humans can, which is why they are so good at getting away from us.

## SIMPLE EYES

Some arthropods have simple eyes instead of compound eyes. Some have both! Simple eyes are usually smaller than compound eyes and are **great at detecting changes in light**—helping bugs figure out what time of day it is.

**Snails** have eyes on the end of stalks, called tentacles. These bug relatives have poor eyesight, so they use a combination of feeling and looking to find their way.

Common garden snail

**Praying mantises** see the world in 3-D, like people. This helps them snatch their prey out of the air as it zooms past.
