

Cave dwellers

Caves are dark, wet, and still. The bugs that live in them are **pecially adapted to help them survive these unique conditions**. They are often blind and colorless, but some have extra-special senses.

Animals that have adapted to life in caves are called troglobites.

Cave millipede

Cave millipede

Like many cave bugs, cave millipedes look white in color. There's no need for them to blend into their dark habitat because cave-dwelling predators can't see them.

Whip spider

Whip spider

A whip spider's long, thin front legs are used for sensing. By gently touching its surroundings, a whip spider can build a picture of its pitch-black world and scuttle around, catching smaller bugs in its enormous jaws.
