

Extreme environments

From freezing glaciers to scorching deserts, and from mountain peaks to the depths of the ocean, **bugs and their close relatives can survive almost anywhere!**

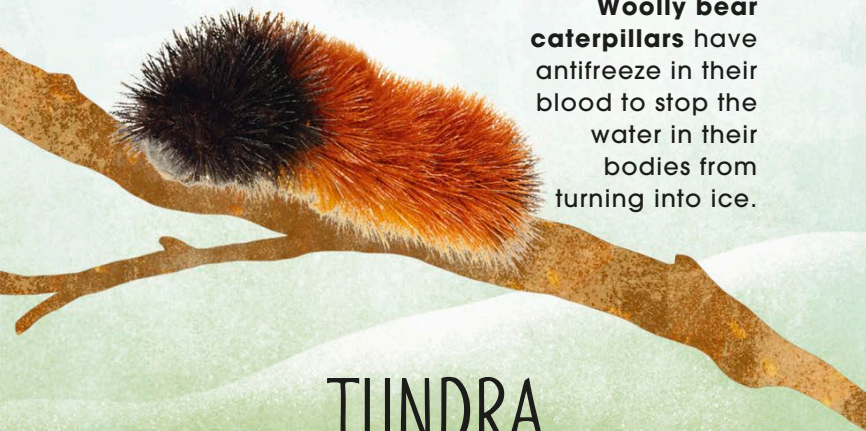

Over many years, layers of fallen snow are compressed and turned to ice, forming glaciers. Tiny **ice worms** are able to wriggle their way through the cracks in glaciers and eat the algae that grows there.

Ice bugs are so well adapted to the cold that just holding them in your warm hands could kill them.

Woolly bear caterpillars have antifreeze in their blood to stop the water in their bodies from turning into ice.

TUNDRA

In a land full of **snow and ice**, where very few plants grow, bugs must cope in the harsh, **freezing winters**.

Fog-basking beetles collect the morning fog on their bodies, then do headstands to drip the liquid into their mouths to drink it.

Flic-flac spiders cartwheel across the sand to escape danger.

Despite their name, **sun spiders** are not actually spiders but ferocious arachnids that can take down venomous bugs like centipedes and scorpions. They avoid the hot desert sun by hunting at night.

DESERT

Hot, dry climates make deserts one of the most challenging habitats for creepy-crawlies to survive.
