

Climate change

Rising global temperatures and changing weather patterns affect the growth of plants and flowers. Sometimes this means that food for bugs is not available in the right place at the right time. If bugs can't find the food they need to survive, then the animals that eat bugs are at risk, too.

Habitat loss

As cities grow, natural spaces are lost, and forests are cut down. There are fewer and fewer places for bugs to live and feed.

Paradise lost

Gardens were once bug paradises. But as people put up more fences, tidy up their lawns, and put down plastic sheets and concrete, it is harder than ever for bugs to survive alongside people.

Harmful chemicals

Pesticides, including insecticides, herbicides, and fungicides, are chemicals used by farmers to keep their crops free of pests, weeds, and diseases. But they can kill the helpful bugs as well as the pests and are particularly harmful to bees.

Chemicals are sprayed on farming land by special aircraft.
