

BOLETALES

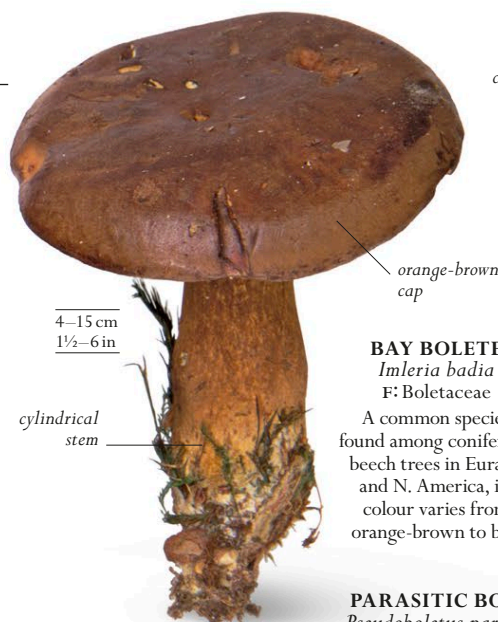

This order contains fleshy fungi and includes those with both pored and gilled fruitbodies, most with cap and stem, but some are crusts, puffballs, or truffle-like. The majority live in association with trees (mycorrhizal), but some feed on dead wood and cause a brown rot, while others are parasitic. The spore-producing layer – the hymenium – is easily loosened from the flesh.

6–14 cm
2¼–5½ in

BITTER BEECH BOLETE
Caloboletus calopus
F: Boletaceae

From Eurasia and western N. America, its cap varies from white to buff. Its yellow pores and cream flesh bruise blue.

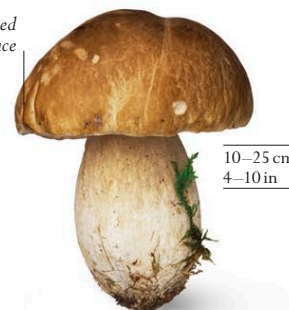

4–15 cm
1½–6 in

cylindrical stem

BAY BOLETE
Imleria badia
F: Boletaceae

A common species found among conifers or beech trees in Eurasia and N. America, its colour varies from orange-brown to bay.

10–25 cm
4–10 in

PENNY BUN
Boletus edulis
F: Boletaceae

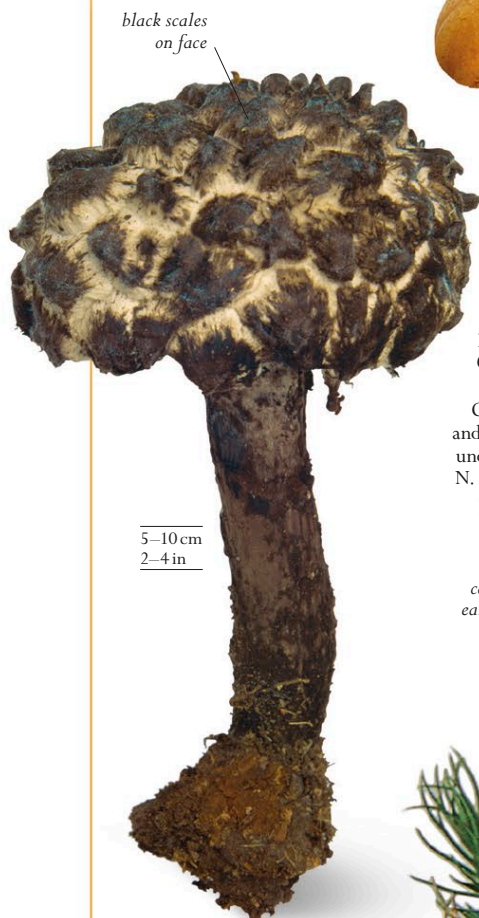

Found worldwide, this species has fine white markings on its stem, unchanging cream flesh, and white pores that mature to yellow.

7–15 cm
2¾–6 in

SUMMER BOLETE
Boletus reticulatus
F: Boletaceae

A cracking, matt, brown cap and a stem with a fine white net extending to its base distinguish this species from Eurasia and eastern N. America.

5–10 cm
2–4 in

OLD MAN OF THE WOODS
Strobilomyces strobilaceus
F: Boletaceae

Found in Eurasia and N. America, this rare species is unmistakable with black woolly scales on its cap and stem, and white tubes.

3–5 cm
1¼–2 in

PEPPERY BOLETE
Chalciporus piperatus
F: Boletaceae

Common under conifers and also found with fly agaric under birches in Eurasia and N. America, it has cinnamon pores and yellow flesh.

6–15 cm
2¼–6 in

BITTER BOLETE
Tylopilus felleus
F: Boletaceae

This species, found in Eurasia and N. America, is characterized by pores that turn pink with age and a strongly netted stem.

PARASITIC BOLETE
Pseudoboletus parasiticus
F: Boletaceae

This small mushroom from Eurasia and N. America grows only on the common earthball, causing its host to become hollow.
