

nostril

wide mouth used to take prey of any size that will fit inside it

male's throat is distended when he produces his loud, trill-like mating call

GLAND >

The enormous parotoid glands – located on each side of the head – secrete a powerful toxin that is distasteful to some predators and lethal to most.

**EAR >**

Toads rely on their hearing to identify potential enemies. At night, it is especially important for females, who locate males by their calls.

**FRONT FOOT ^**

In the breeding season, males develop dark, horny nuptial pads on their first three fingers. These enable them to clasp females firmly during mating.

**IRIDESCENT IRIS**

Like most toads, cane toads have large, protruding eyes. They have very good eyesight, enabling them to detect small, moving objects and to lunge accurately at their insect prey.

**^ NOSTRIL**

The cane toad relies more on its sense of smell to find food than other toads – and breathes more with its lungs than with its skin.

< HIND FOOT

The long toes on the hind foot, each with a horny tip, provide a firm grip on the ground when a toad pushes off to hop or jump.

prominent warts

**WEBBING >**

Compared with many other frogs and toads, cane toads have poorly developed webbing between their toes. This reflects the relatively small part of their lives spent in water.
