

crystal of red garnet

GARNET PERIDOTITE

Peridotite has a composition similar to that of Earth's upper mantle. This dense, greenish variety is made of dark minerals including garnets, olivine, and pyroxenes.

**DUNITE**

Composed almost entirely of olivine, this rock is dark green or brown, with a medium-grained texture. It usually includes a little chromite.

green olivine crystals

PERIDOTITE

A dark, dense rock composed mainly of olivine and pyroxenes, peridotite is coarse-grained and forms slowly at great depth.

pink orthoclase feldspar

**ADAMELLITE**

This type of granite forms at depth with crystals of quartz, micas, and feldspars. One-third to two-thirds of the total feldspar content is plagioclase.

**GRAPHIC GRANITE**

This coarse-grained rock contains quartz and feldspars, whose intergrowth results in a graphic texture, vaguely resembling runic writing. It also contains micas.

dark hornblende

HORNBLLENDE GRANITE

Granite typically contains quartz, feldspars, and micas. This variety also contains hornblende, a member of the amphibole mineral group.

**KIMBERLITE**

Dark-coloured and coarse-grained, kimberlite has a very low silica content. Of variable composition, it is the world's main source of diamonds.

**FELSITE**

Fine-grained felsite forms in sheet-like intrusions, sills and dykes. Pale in colour, it is composed mainly of feldspars and quartz.

**ANORTHOSITE**

Pale-coloured, anorthosite is composed mainly of large crystals of plagioclase feldspars. It can also contain olivine and augite.

PEGMATITE

Pegmatites are very coarse-grained rocks, formed from residual liquid magma after most of a granite intrusion has cooled and crystallized. Some pegmatites are an important source of gemstones.

PORPHYRITIC GRANITE

A pale-coloured rock composed of feldspars, quartz, and micas, porphyritic granite has large, well-formed crystals set into the matrix.
