

A cold front

Fronts usually come in pairs. Often there is only a brief gap between one front passing and the next arriving. The first is a “warm” front because it brings warmer air. The second is a “cold” front, and brings colder air and sometimes even stormier weather than the warm front.

Stratocumulus clouds bring occasional drizzle.

On the move

On a weather map, a cold front is a line with blue spikes. The spikes show which way the cold air is moving.

Brief relief

As the warm front moves away, the rain (or snow) stops and it gets warmer. Near the coast it stays cloudy, and there may be drizzling rain.

In summer, inland, the Sun comes out and it can get hot after the warm front has moved away.
