

Soft test method for micro-LED wafers

Researchers at Tianjin University (Tianjin, China) have developed a soft-contact, non-destructive testing method using a flexible 3D probe array. Applying an ultra-low pressure of just 0.9MPa, it preserves delicate wafer surfaces

during high-throughput electrical testing. This innovation extends probe durability beyond a million cycles and enables accurate yield screening without scratches. A complementary measurement system boosts practicality, paving the way for commercial adoption in micro-LEDs and broader flexible electronics inspection.

BSNL delivers 980Mbps downloads for 4K streaming, gaming, and hybrid work

BSNL's (New Delhi, India) Quantum 5G FWA delivers 980Mbps downloads with sub-10ms latency—ideal for 4K streaming, gaming, and hybrid work. Featuring a SIM-less, plug-and-play setup, it eliminates cabling hassles using India-made hardware under the Atmanirbhar Bharat initiative. The pilot, now live in Hyderabad, is set to expand to six more cities by 2025. With enterprise-ready capabilities on a standalone 5G core, BSNL targets both home users and smart industry use cases.

Keysight platform now includes a new TLS exploit

Keysight uncovers hidden transport layer security covert channel threat evading network defenses (Credit: www.keysight.com)

Keysight's ATI platform now includes a newly discovered TLS exploit that allows attackers to reorder handshake parameters, bypassing security without requiring code injection. This covert

method is hard for firewalls to detect, but Keysight enables safe simulation in lab environments. Security teams can test and fine-tune defences before real-world exposure.

With over 10,400 attack simulations, daily malware updates, and flexible configurations, ATI helps organisations stay ahead of threats, especially those hiding within trusted encryption protocols like TLS.

Skin-like electronic material with self-healing powers

Researchers at DTU (Kongens Lyngby, Denmark) have developed a groundbreaking electronic skin material that's flexible, stretchable, and self-healing, ideal for wearables,

soft robotics, and medical technology. Made by blending graphene with PEDOT:PSS, it mimics the softness and resilience of real skin. It heals in seconds, stretches 6x its length, and senses pressure, temperature, and pH. Enables smart bandages, prosthetic sensors, and next-gen implants. With efforts underway to scale production, this innovation could redefine how electronics interact with the human body.

Robots could one day crawl across the moon

University of Colorado Boulder researchers are using VR to train people to control Moon-bound robots, without leaving campus. Participants operating a digital twin of

the 'Armstrong' robot in VR completed tasks 28% faster and with less stress. Built in Unity, the simulation mimics real robot behaviour and helps users prepare for lunar missions. Now, the team is tackling an even tougher task: virtually simulating lunar dust for future rover operations. Students play a key role in building tomorrow's space tools today.
