Automotive 2D dual Hall effect latch IC

As vehicles become more electrified and automated, the number of small motors controlling power windows, sunroofs, and liftgates is increasing, creating a need for compact, accurate,

and reliable motion detection. Traditional systems often use two separate Hall effect ICs to detect magnetic flux in different directions, which adds complexity, cost, and space constraints. ABlic's new S-57W1/W2 series addresses this by integrating dual-direction detection into a single chip that converts mechanical rotation into electrical signals, accurately capturing motor speed and direction from startup. With industry-leading magnetic sensitivity and the thinnest 2D dual Hall latch package available, it enables high-resolution, space-efficient motor control for automotive engineers designing the next generation of precise, responsive motion systems.

AI supercomputer

AI developers are encountering the limitations of traditional PCs and workstations as models become too large to run locally, forcing them to rely on the

cloud for training and inference. This slows experimentation, increases costs, and creates dependency on external infrastructure. Nvidia's DGX Spark

solves this by bringing data centre-level performance to the desktop, offering a petaflop of AI power and 128GB unified memory. It enables local inference on models with up to 200 billion parameters and fine-tuning of models with up to 70 billion parameters, allowing developers to build, train, and test complex AI agents or applications entirely on-site without relying on the cloud.

Adaptive analogue modules

Engineers often need analogue circuits but want to avoid firmware or digital

control. Okika Devices' Chameleon modules solve this by providing pre-programmed analogue functions in a package, combining a field programmable analogue array (FPAA) with on-board nonvolatile memory, an oscillator, and reconfiguration circuitry. Designers can use them as

fixed-function analogue blocks without a microcontroller, or reprogram them in-system via a 3.3V SPI interface for customisation and iteration. The modules are suited for a range of applications, including programmable active filter networks, sensor signal conditioning and linearisation, industrial automation, adaptive control, and prototyping, giving engineers analogue flexibility while reducing development time and complexity.

Single-chip wireless platform

As connectivity standards evolve, device makers struggle to keep products up-to-date without redesigning their

hardware, often requiring multiple chips to add features or adapt to new protocols, which increases both cost and complexity. Microchip Technology's PIC32-BZ6 MCU solves this by providing a single platform for multiprotocol wired and wireless connectivity, with built-in analogue peripherals for motor control, touch and graphics support for interfaces, and memory for workloads and over-the-air firmware updates. By consolidating these functions into one chip, it simplifies RF design, reduces development effort, and enables scalable, upgradeable devices that can evolve with market demands.
