

Nishita Baliarsingh and Nikita Baliarsingh, Founders, with Nexus battery pack

The company plans to scale up this facility in the next three to four months. To accelerate development and increase capacity, the team also rents specialised equipment and laboratory space across the country, as pilot lines offer limited throughput. However, most production still comes from its own manufacturing line.

Speaking about revenue, Nikita disclosed, “Our batteries are currently in trial, testing, and pilot stages, and are not yet commercially sold. We do have some marginal pilot revenues, but to begin full commercial sales, the necessary certifications must be completed. At this stage, operations remain focused on pilots and trials rather

than full-scale commercial sales.”

The company began with grants from the government of India and the government of Odisha. Its first round of funding came through programmes from Startup Odisha and multiple departments of the government of India, including MeitY, DBT, and BIRAC. An equity round followed in 2022, with subsequent rounds thereafter. “We continue to receive significant government support, with a few PSUs involved in tests and trials, along with direct collaboration with government departments in Odisha for various projects,” Nikita said.

In the short term, the company plans to expand pilot manufacturing capacity by acquiring larger production lines and collaborating with institutes that already operate manufacturing facilities. Recruitment will also be a key focus, as expansion will require additional team members. Over the long term, the startup aims to evolve into a broad-based energy innovation company, extending its impact beyond batteries into adjacent segments where it can contribute meaningfully.

3 A FULL DIAGNOSTIC LAB THAT EASILY FITS YOUR POCKET

By combining deep electronics engineering with point-of-care design, the system delivers fast, affordable diagnostics at the point of need—without bulky machines, complex infrastructure, or high upfront costs.

In 2015, Ashish Raichura faced a personal crisis. His father required routine monitoring for vital signs such as blood pressure, heart rate, and temperature, and was later diagnosed with Alzheimer’s. The experience exposed a glaring gap in India’s diagnostic testing ecosystem, one that was expensive, fragmented, and largely inaccessible beyond urban centres.

From this challenge, Scanbo emerged. Formally incorporated in 2019, the company set out with a

clear mission: to compress the capabilities of a full diagnostic laboratory into an affordable, portable point-of-care device that could function anywhere. As Raichura describes it, Scanbo was “born out of a deeply personal healthcare challenge and refined through years of hard engineering.”

The approach deliberately prioritises hardware over apps. While many healthcare solutions rely on external gadgets and inconsistent data streams, Scanbo developed the

D8, a handheld device weighing under 100 grams, lighter than most smartphones. The device independently captures eight key diagnostics: electrocardiogram (ECG), respiration rate, heart rate variability (HRV), blood pressure, heart rate, blood oxygen saturation (SpO₂), blood glucose, and body temperature. Together, these enable rapid screening, triage, and longitudinal monitoring.

The path to this level of integration was far from straightforward.
