

unencrypted connections and enforces the latest TLS standards on all connected devices. It is designed to enable IoT applications to automatically follow best security practices, requiring no additional effort from developers. Furthermore, Anedya manages its own public key infrastructure (PKI) chains to issue and control device certificates—an advantage over relying on third-party certification services, which are often costlier and not optimised for IoT environments. Users can also import and manage their certificate chains directly within the platform.

According to Chinmaya, Anedya simplifies device provisioning with a flexible range of options. Devices can be pre-registered by manufacturers, auto-register upon activation, or connect via user-friendly interfaces, such as Wi-Fi hotspots and smart assistants. The system maintains a persistent connection until the device is explicitly reset or replaced.

Anedya also streamlines IoT device management through its comprehensive OTA update solution, a critical need in modern IoT environments. The system goes beyond firmware updates, supporting efficient

Chinmaya Mahanta, Co-Founder of Anedya Systems (extreme right), with his team members

and secure deployment of executables, media, and zip archives across thousands of devices. Key features include asset versioning, targeted rollouts, phased deployments, automatic aborts with rollback, and complete lifecycle tracking from deployment to installation.

The platform has already been successfully deployed across multiple industries. More than ten use cases have been built using Anedya's

stack, and over 25,000 IoT devices are currently running. Notable applications include smart streetlight management, cold rooms, connected vehicles, industrial automation, medical devices, smart agriculture, and drone telematics.

Markand notes that Anedya generates revenue primarily from B2B clients through a pay-as-you-go model, with no upfront or subscription fees. Charges are based on actual usage, specifically, the number of connected devices, data storage, queries, and commands, tailored to each use case. On average, the cost per device ranges from ₹10 to ₹200 per year, depending on the specific application.

To support early-stage adoption, especially by students and startups, Anedya offers 100 free lifetime devices and \$50 in evaluation credits. Thousands of students have used the platform to build academic or hobbyist IoT models. "We want to reach a million students with our Made-in-India IoT platform," says Chinmaya.

2 GLOVATRIX TURNING SIGN LANGUAGE INTO SPEECH WITH SMART GLOVES

Smart gloves powered by AI and technology may soon dissolve the barriers between the deaf and the hearing world.

The idea to work for the deaf community began in Aishwarya Karnataki's school days, when she met a boy from the special needs section who used sign language. This prompted her to learn it so she could communicate with him. Years later, while studying electronics and building a robot, she thought of creating gloves that could

translate sign language into speech. That idea evolved into Glovatrix, a company she started with Parikshit Sohoni in Pune to help the deaf communicate. They began work in January 2020 and launched the company in April 2021.

Together, they developed AI-based gloves that convert sign language into voice so everyone

can understand what deaf people want to say. The gloves also have a microphone that converts spoken words into text, helping deaf people understand others. When asked about the name of their startup, Aishwarya said, "We grew up watching a cartoon called Swat Kats. It had a special glove that could shoot missiles. That glove gave us the idea to make our own gloves—not for fighting, but to help people talk to each other."

AI is key to how the gloves work.
