sensor is connected to the ESP32 board, as shown in Fig. 4. Similarly, you can use the MQ135 sensor in the ESP32 board, as shown in Fig. 5 for the prototype. Data of the prototype shown in Fig. 4 and Fig. 5 can be seen on Fig. 6 and Fig. 7 through ESPHome dashboard.

All *.yaml files for this automation system can be downloaded from *electronicsforu.com*. To explore their human-readable structure, these files can be opened in a text

editor (e.g., Notepad, Nano, or VS Code).

Each YAML file defines a specific ESPHome device's configuration, including Wi-Fi details, sensors, and output controls. The structure is intuitive, making modifications straightforward.

ESPHome dashboard view

For each YAML file, an entry appears on the ESPHome device page. Available devices are marked as 'ONLINE' or 'OFFLINE'. Clicking on an 'ONLINE' device opens its configuration page.

AHT10 sensor is a temperature humidity sensor similar to the DHT22 sensor; only AHT10 is an I2C device and is more precise and stable than the DHT22 sensor. When the ESP32 Bluetooth Proxy configuration is uploaded to the ESP32 board, the device will appear

as 'ONLINE' at the top of the second column of the ESPHome dashboard. Unlike other devices, it does not initially display a 'visit' button. However, once it detects a BLE signal from a nearby device, the 'visit' button will appear to view the received data.

This automation system showcases the versatility of ESPHome software and the simplicity of YAML-based automation. Future developments will explore more complex automation, including additional BLE device integration and advanced Bluetooth Proxy features. The possibilities with ESPHome and YAML configurations are vast. **EFY**
