“Frequent **CHARGING AND DISCHARGING** Affect Battery Life; **PROPER CHARGING** Practices Can Maintain **BATTERY HEALTH**”

How can battery life be maximised? Should it be fully drained before charging? What steps help maintain battery health? Anshuman Divyanshu from Exicom shares insights in an interview with EFY's Nitisha.

ANSHUMAN DIVYANSHU
CEO, EXICOM

What precautions should be taken to ensure the longevity of a battery?

From a safety perspective, several key factors are crucial. One important aspect is the power source. Improper charging and discharging practices can significantly impact battery life, much like mobile phones, where charging before the battery is fully drained is recommended. Allowing a battery to discharge completely can reduce its lifespan. However, as battery technology evolves, manufacturers are incorporating safeguards to enhance the durability of battery packs.

Customers can help maintain battery health by following proper charging practices. This includes using a stable power source with appropriate voltage and current, preferably with copper wiring. Charging under these conditions

helps prevent deterioration and extends the lifespan of the battery pack.

What is the typical lifespan of battery systems?

Battery systems typically come with warranties ranging from three to four years. Batteries store energy, and there is a finite limit to how much energy they can hold and the number of charge-discharge cycles they can undergo. Under normal usage conditions, a battery is expected to last between five and seven years. However, in cases of heavy usage, the lifespan may be reduced to anywhere between three and five years.

How do your chargers ensure energy efficiency and minimise power wastage?

Minimising energy loss during the charging process is essential for energy efficiency. In DC chargers, AC-to-DC conversion inherently causes some energy loss. To address this, we adhere to global and Indian standards to reduce energy losses. We use high-quality components designed to consume less electricity and minimise wastage.

All our DC chargers are now equipped with dynamic load-sharing capability, ensuring optimal power distribution when two vehicles with different power demands are connected. The system delivers the exact power required by each vehicle, preventing wastage. For instance, if a vehicle requires low power while the charger outputs high power, it leads to inefficiency. Dynamic load sharing optimises power delivery,
