high-end projectors, often called ‘life-style screenless televisions,’ deliver visuals that rival traditional TVs.

At the heart of this transformation is ALPD, which improves both image quality and energy efficiency. Whereas older models depended on very high brightness to overcome ambient light, ALPD achieves vivid colours at lower brightness levels—thanks to a more efficient light engine—delivering better visuals with reduced energy consumption.

For example, Optoma laser projectors use lasers to create the image. In many situations, the brightness of a laser model can appear nearly twice as bright as that of a lamp-based projector.

Alongside ALPD, two other technologies—Trichroma laser and MALC laser—are gaining ground.

Both use RGB (red, green, blue) laser light to achieve lifelike colour reproduction. The key difference lies in their design. ALPD supports both single- and triple-laser MALC systems, while Trichroma and MALC are purely triple-laser platforms. Think of them as different operating systems—distinct in build but similar in output.

A major challenge in triple-laser systems is aligning the three colour channels. However, with the help of AI and improved software, calibration is now much easier. Modern projectors let users fine-tune individual colours and switch between preset modes like Dynamic, Vivid, and Sports. Advanced options, such as Filmmaker Mode, Director’s Cut, IMAX Enhanced, and Dolby Vision, automatically adjust colour and tone

to match the content’s original look. For example, when streaming a high-resolution film like Avatar, the projector uses Dolby Vision to fine-tune colour in real time.

One simple example is the Christie M 4K RGB projector. It uses RGB laser light, displays 4K images, and features smart capabilities to accurately align colours.

Despite different names and designs, all three share a common goal: better colour, clarity, and image quality, making today’s projectors a strong alternative to traditional televisions.

Projectors in your pocket

Mini and pocket projectors—often called pico projectors (short for ‘picture in, carry out’)—are reshaping how people watch content on
