Adoption of advanced projection technologies

Apotronics, a global leader in laser projection and a 60% partner in Formovie (with Xiaomi holding 40%), introduced ALPD—used in over 100,000 cinema halls—into the home projector market. This commercial-grade technology reduces pixelation, rainbow artefacts, and visual noise in home cinema.

- **Formovie.** First to bring ALPD to home projection (2021)
- **JMGO (Jimgo).** Uses its own Triple MALC Laser tech
- **Hisense.** Developed Trichroma Laser technology; also manufactures for other major projector brands

New-generation 'screenless TVs' offer significantly better image quality compared to older projectors. The difference is visible in clarity, brightness, and colour precision, marking a sharp divide between traditional and modern projection systems.

or share visuals across networked projectors.

UST projectors have become increasingly common. Positioned on a table near the wall, they can display images larger than 2.5-metre (100-inches). Setup is quick, brightness is high, and many manufacturers now offer them.

One example is the Formovie THEATER, a 2800-lumen UST projector with built-in Android TV that operates without any additional media box.

UST projectors cost more than standard ones. The internal components are similar, but the lens is more complex, enabling projection of large images from very short distances. They work well in tight spaces, sometimes just 30cm (1 foot) from the wall, with throw ratios between 0.25:1 and 0.5:1.

Projectors with AI inside

Artificial intelligence has long been part of smart projectors, but its role has expanded significantly in modern models. Early projectors required manual setup, especially when projecting from an angle, which made alignment and focusing time-consuming. That is no longer the case.

Today's lifestyle projectors use AI to auto-correct and optimise the image. Whether tilted to the side or pointed at the ceiling, the projector detects the surface and adjusts the frame to a perfect 16:9 aspect ratio. Screen detection eliminates the need for manual alignment; press

a button, and the image fits the screen in under 10 seconds. Focus and keystone corrections are made instantly.

For instance, the BenQ W2720i uses a built-in camera to assess ambient light and adjusts the screen image accordingly, functioning seamlessly in both bright and dim rooms.

JMGO projectors use triple-laser MALC engines to ensure colour accuracy and consistent brightness. AI-powered auto-alignment with a motorised gimbal simplifies setup, demonstrating how smart features are transforming projector usability.

Another valuable feature is object avoidance. If a plug-socket or piece of wall décor blocks part of the surface, the projector detects it and shifts the image accordingly, no manual input required.

AI also enhances content quality. Built-in processors adjust settings for viewing modes like Sport, Dynamic, or Vivid. Advanced features such as IMAX Enhanced, Dolby Vision, Director's Cut, and Filmmaker Mode apply colour and contrast profiles as intended by content creators.

These projectors are entirely wireless, except for power, and operate on platforms like Google TV or VEDA. Once connected to Wi-Fi, they function like smart TVs. A voice-enabled remote allows users to search for content with commands like 'Show me Tom Cruise movies,' returning results across various apps, including Netflix, Prime
