

(L to R) Siddharth Goel, Co-Founder, B.Tech, IIT Kanpur, looks after all production, manufacturing, and new product development; Anmay Shahlot, Co-Founder, MBA, IIM Indore, looks after sales, marketing and growth; Aditi Agrawal, Co-Founder, B.Arch, OP Jindal School, looks after operations and design

which is the basis for their performance claims. However, actual results can vary depending on factors like wind speed, air quality, temperature, and humidity, just as with any air purifier.

Miniaturising the air purifier posed challenges, especially with battery life. The team upgraded to a 400mAh battery, giving the device a 48-hour runtime. With 10-12 hours of daily use, the battery can last

about four days without charging, greatly improving convenience and reliability.

On sales and revenue, Anmay explains, “We officially launched in December last year. While we have sold over 10,000 units so far, it does not reflect the bigger picture. The first full season for air purification is yet to come, and sales are projected to grow significantly as air quality worsens during this

period. As the demand for products like these increases, we expect even stronger growth in the coming months.”

Speaking about the challenges the startup faces, Anmay says, “I think awareness is still a big challenge. Many people do not realise how bad the air quality is. Besides awareness, product development and manufacturing in India are also challenging, especially for electronics. Working with different vendors can be difficult, and sometimes the quality or finish from vendors is not as expected. So, there are many hurdles on both the awareness and manufacturing sides.”

Looking ahead, the team is focusing on growth and scaling. They are hiring more people for marketing and operations, investing heavily in marketing campaigns, and increasing production capacity to meet the expected demand in the last quarter of the year. All these steps are aimed at ensuring that the product reaches more users and performs well during the high-pollution season.

3 “WITH OUR OPTICS, INDIA CAN RELY ON HOMEGROWN TECHNOLOGY INSTEAD OF IMPORTS”

Imagine satellites, drones, and ground systems capturing the world with absolute clarity and turning that vision into actionable data, all made in India. EON Space Labs is bringing that vision to life with cutting-edge cameras and sensors that are redefining surveillance, Earth observation, and defence technology.

EON Space Labs is an Indian deep-tech startup focused on developing a multi-domain Earth Observation Network. The company designs and manufactures optical payloads for satellites, drones, and UAVs, providing solutions for long-range surveillance, Earth observation, and defence applications. EON’s technology

spans Earth observation, infrared imaging, and data analytics solutions across space, aerial, and ground platforms. Products like MIRA, Argus, LUMIRA, and BUHO are tailored for each operational environment.

For space applications, EON is developing optical systems that can be mounted on satellite payloads

for EO/IR observation, agricultural monitoring, and strategic surveillance. Their optical payloads have dual-use applications for civilian industries and defence. In agriculture, these systems can measure soil composition, water content, and crop health, offering actionable insights for precision farming. In defence, they can be deployed
